

ABSTRACT

A closing slider 30A for closing a zipper of a plastic bag, the zipper having a groove and a protrusion, which are mutually engageable with each other, provided on mutually opposite inner surfaces of flaps formed at an open portion of the plastic bag. The closing slider has a couple of side legs 31 located outside the flaps, and a center leg 35 located between the flaps and having a length not reaching the zipper. Side portions of the side legs 31 are partly cut off 31a, and thereby, a side portion of the center leg is exposed 35a. Slits may be made in a top of the slider in such a way to extend to a side of the slider, so that the flaps can be inserted between the center leg and the respective side legs through the slits.
